Abstract

Digital transformation is increasingly regarded as a strategic requirement for small and medium enterprises (SMEs), yet the relationship between technology adoption and sustained competitive advantage is neither automatic nor uniform. This paper examines how SMEs can convert digital technologies into defensible competitive outcomes through complementary organisational resources, dynamic capabilities, business model innovation, and effective governance. The study adopts a qualitative, integrative review design based exclusively on secondary sources, including peer-reviewed research and institutional publications. It synthesises resource-based and dynamic-capabilities perspectives with research on digital business strategy, SME business model innovation, and the barriers documented by the Organisation for Economic Co-operation and Development (OECD). The analysis indicates that digital tools can improve operational efficiency, customer access, information quality, responsiveness, and innovation; however, the strategic value depends on alignment with business objectives, workforce skills, leadership commitment, process redesign, and data governance. The paper proposes a capability-based framework in which digital resources are transformed into competitive outcomes through sensing, seizing, and reconfiguring activities. It also identifies recurring constraints, including limited finance, skills shortages, cybersecurity exposure, technology fragmentation, and dependence on external platforms. The study concludes that SMEs should pursue staged, measurable transformation rather than technology acquisition for its own sake. Because the paper uses secondary evidence, its findings are analytical propositions rather than new empirical estimates. The framework offers practical guidance for SME managers and a basis for future sector-specific empirical testing.

Keywords: *digital transformation; small and medium enterprises; competitive advantage; dynamic capabilities; digital business strategy; business model innovation; organisational agility.*

1. Introduction

Small and medium enterprises occupy a central position in employment, entrepreneurship, supply chains, and local economic development. Their scale can support flexibility, close customer relationships, and rapid managerial decisions. At the same time, SMEs often operate with thinner financial reserves, limited specialist expertise, and less bargaining power than large corporations. Digital technologies have changed the competitive environment in which these firms operate. Cloud computing, e-commerce, digital payments, enterprise applications, social media, data analytics, artificial intelligence, and connected supply-chain platforms can lower coordination costs and expand access to customers and partners. Yet the benefits depend on the firm's ability to integrate these tools into its strategy and operating model.

Digital transformation should be distinguished from the mere conversion of analogue information into digital form. Digitisation converts information into digital data; digitalisation uses digital tools to improve or redesign existing activities; digital transformation involves broader changes in organisational processes, value propositions, capabilities, and business models (Verhoef et al., 2021). Vial (2019) similarly presents digital transformation as a process in which digital technologies trigger significant changes to organisational properties and value-creation pathways. This distinction matters for SMEs because buying software or opening a social-media account may improve a task without changing the firm's competitive position.

The strategic question is therefore not whether an SME uses technology, but whether it develops a distinctive capacity to use technology better, faster, or more appropriately than competitors. The resource-based view argues that sustained advantage arises from valuable resources that are not evenly distributed and are difficult to imitate or substitute (Barney, 1991). Technology itself is often purchasable by competitors. Consequently, the more defensible advantage may lie in complementary assets: trusted customer data, process knowledge,

employee expertise, supplier relationships, a distinctive service model, and the organisational routines that combine them.

The dynamic-capabilities perspective extends this argument by emphasising the capacity to sense opportunities and threats, seize opportunities through investment and business design, and reconfigure assets as conditions change (Teece et al., 1997). For SMEs, this perspective is especially relevant because digital markets evolve quickly and firms cannot rely indefinitely on a single technology or channel. Digital transformation can improve competitiveness when it helps a firm learn from customers, coordinate its operations, adapt its offer, and create value in ways that are meaningful to a defined market.

However, transformation can also produce disappointing results. SMEs may adopt disconnected applications, underestimate implementation costs, lack staff who can interpret data, or expose themselves to cyber and privacy risks. OECD research identifies persistent SME barriers such as limited awareness, skills gaps, financing constraints, infrastructure issues, and concerns about digital security and data protection (OECD, 2021, 2024). The gap between basic adoption and strategic transformation is therefore important: access to a tool does not ensure the managerial and organisational capacity to use it productively.

This paper analyses the mechanisms through which digital transformation may create competitive advantage in SMEs. It brings together strategic-management theory, digital-business research, SME-focused empirical studies, and institutional evidence. The paper is structured as follows: literature is reviewed; objectives and the research gap are specified; the secondary-research methodology is explained; evidence is synthesised thematically; and findings, implications, limitations, and future research directions are presented.

2. Review of Literature

2.1 Resource-based view and the foundations of advantage

Barney (1991) argues that firm resources can support sustained competitive advantage when they are valuable, rare, imperfectly imitable, and not strategically substitutable. This framework helps explain why the same digital application may produce different outcomes across firms. A cloud accounting package may be widely available and therefore unlikely to be a source of rarity on its own. However, a firm's accumulated transaction history, ability to forecast demand, integrated supplier routines, or trusted digital customer experience may be more difficult to replicate. The implication is that managers should evaluate technologies as enablers of a resource system rather than as isolated assets.

Bharadwaj (2000) applies a resource-based perspective to information technology capability and distinguishes IT infrastructure, human IT resources, and IT-enabled intangibles. Her empirical investigation found that firms with stronger IT capability tended to outperform a matched comparison group on several performance measures. Although the study is not confined to SMEs, it supports the view that technological infrastructure must be combined with people and intangible organisational resources. For smaller firms, this suggests that training, data discipline, and process ownership are as important as software selection.

2.2 Dynamic capabilities and organisational adaptation

Teece et al. (1997) locate competitive advantage in organisational processes, asset positions, and the paths through which firms develop. Their dynamic-capabilities framework is relevant where technological change alters customer expectations and industry structures. A digital SME must sense changes in customer behaviour and competitor activity, seize opportunities by allocating resources to suitable solutions, and reconfigure routines, roles, and partnerships. These activities are iterative rather than linear. A firm that launches an online sales channel but does not revise inventory planning, customer support, or fulfilment may create new demand without building the capacity to serve it.

The dynamic-capabilities view also guards against technological determinism. Competitive advantage does not follow automatically from owning a new technology. It depends on managerial judgement, organisational learning, and the ability to redeploy resources. This is particularly important for SMEs, where the owner-manager may play a central role in investment decisions and organisational change.

2.3 Digital transformation as strategic and organisational change

Vial (2019) synthesises digital-transformation research and describes how digital technologies can disrupt existing value-creation paths, requiring organisations to respond through strategic and structural change. Verhoef et al. (2021) distinguish digitisation, digitalisation, and digital transformation and highlight changes in business models, organisational structures, capabilities, and performance measures. Both perspectives caution against reducing transformation to technology implementation. They also imply that measurement should extend beyond the number of tools adopted to include changes in customer value, process performance, innovation, and organisational capability.

Bharadwaj et al. (2013) argue that digital business strategy increasingly fuses business and IT strategy. Digital technologies affect the scope, scale, speed, and sources of value creation, making technology a strategic concern rather than a subordinate functional activity. For SMEs, this means that decisions about e-commerce, analytics, digital payments, or automation should be linked to target segments, value propositions, operating economics, and competitive positioning.

2.4 SME business model innovation and performance

Bouwman et al. (2018) examined 338 European SMEs using social media and big data to innovate business models. Their findings indicate that digitalisation-driven business model innovation was associated with positive business-performance effects, while also showing the importance of internal strategic and innovation-related motives. The study helps move the discussion beyond adoption rates by linking digital tools to changes in how firms create and deliver value. Nevertheless, its sample and focus on firms already using relevant technologies mean that results should not be generalised to every SME or sector without qualification.

Bouwman et al. (2019) investigated 321 European SMEs and found that allocating resources to business-model experimentation and engaging in strategy implementation were positively related to overall firm performance. The contribution is important because it highlights implementation practices rather than technology presence alone. It also suggests that experimentation requires resources, a challenge for smaller firms. Managers must balance the need to test new models with the risks of diverting scarce time and capital from core operations.

Matarazzo et al. (2021b) studied three Italian SMEs and found that digital tools supported business-model innovation, new distribution channels, and internationalisation, with social media playing an important role in market access. The case-study design provides contextual insight into how digitalisation changes business activity, but the small number of firms limits statistical generalisation. Together, these studies suggest that digital transformation may enable new routes to market, but outcomes depend on sector, strategy, and the firm's capacity to execute.

2.5 SME digitalisation barriers and institutional evidence

The OECD's report on SME digital transformation documents a persistent digital gap between SMEs and larger firms. It identifies barriers involving infrastructure, interoperability, awareness, data culture, skills, financing, and uncertainty about security and liability (OECD, 2021). Kergroach (2021) likewise notes that SME digital adoption often remains concentrated in basic services and that gaps widen as technologies become more sophisticated. The 2024 OECD D4SME survey further examines digital journeys, resilience, artificial intelligence, and data use across participating economies, showing why SME digitalisation must be understood as an evolving process rather than a single adoption decision (OECD, 2024).

These institutional sources add scale and policy context to firm-level studies. They also underline heterogeneity: a digitally advanced medium-sized exporter and a microenterprise with limited connectivity face different constraints. A uniform transformation model is therefore unlikely to be effective. Support should be proportionate to firm size, sector, digital maturity, and exposure to customers and supply chains.

2.6 Synthesis of the literature

The literature converges on three propositions. First, digital technology can improve access to information, customers, and operational coordination. Second, the conversion of those resources into competitive outcomes requires complementary capabilities, including leadership, skills, process redesign, and learning. Third, benefits

are contingent on the firm's context and can be offset by implementation costs, security risks, and weak strategic fit. The present study integrates these propositions into a framework that treats competitive advantage as an outcome of the interaction between digital resources, organisational capabilities, and market-facing value creation.

3. Research Methodology

3.1 Research design and approach

The study adopts a qualitative, integrative literature-review design. An integrative review is appropriate because the research question spans strategic management, information systems, entrepreneurship, SME management, and public policy. The objective is to synthesise complementary explanations and identify recurring relationships rather than estimate a pooled statistical effect. The approach is interpretive and analytical: published findings are compared, grouped into themes, and used to construct a conceptual framework.

3.2 Data sources and source selection

The study uses secondary data only. The evidence base comprises peer-reviewed journal articles and institutional publications that are directly relevant to digital transformation, competitive advantage, digital business strategy, SME business-model innovation, and digitalisation barriers. Core academic sources include foundational work on the resource-based view and dynamic capabilities, broad reviews of digital transformation, and SME-focused studies by Bouwman and colleagues and Matarazzo et al. Institutional evidence is drawn primarily from OECD publications. Bibliographic details and DOI or publisher records were checked against publisher, journal, or institutional pages where available.

Sources were selected purposively for conceptual relevance, scholarly credibility, and contribution to the study objectives. Foundational works were retained even when older because they establish the theoretical basis of competitive advantage and dynamic capabilities. More recent sources were included to capture current digital-transformation debates and SME constraints. This is not presented as a PRISMA systematic review: no exhaustive database search, duplicate-screening protocol, or reproducible screening count was conducted. Accordingly, the paper avoids claiming comprehensive coverage of all published studies.

3.3 Inclusion and exclusion principles

Included sources address at least one of the following: (a) the strategic value of digital or IT capabilities; (b) digital transformation as organisational change; (c) digitalisation and business-model innovation in SMEs; or (d) institutional barriers and policy conditions affecting SME digitalisation. Sources with unclear provenance or unverifiable bibliographic details were not used. General technology commentary without a clear connection to business strategy or SME outcomes was excluded from the analytical core.

3.4 Analytical procedure

The selected literature was analysed through thematic synthesis. First, each source was reviewed for its research focus, theoretical lens, context, main contribution, and limitations. Second, findings were coded into themes: digital resources; leadership and workforce capabilities; sensing, seizing, and reconfiguring; process and business-model innovation; customer and market outcomes; barriers and governance. Third, the themes were compared to identify points of convergence and tension. Finally, a conceptual framework and implementation roadmap were developed from the synthesis.

3.5 Reliability, validity, and ethical considerations

Credibility was supported by prioritising peer-reviewed articles and institutional reports, cross-checking key bibliographic details, and distinguishing authors' reported empirical findings from the present paper's interpretation. No primary survey, interview, company dataset, or experiment was conducted. Therefore, no participant consent or primary-data ethics approval was required. The study does not fabricate sample sizes, response rates, effect sizes, or financial returns. The conceptual tables and diagrams are original analytical representations of the reviewed literature.

3.6 Methodological limitations

The review is selective and interpretive rather than exhaustive. The included empirical studies differ in geography, sector, sample, and operationalisation of digital transformation, making direct comparison difficult. Several influential studies focus on European SMEs or firms already engaged in digital activity, while institutional evidence may aggregate firms with different definitions and levels of digital maturity. The conclusions should therefore be treated as theoretically grounded propositions, not universal causal claims. Future research should test the framework with longitudinal, multi-country, and sector-specific SME data.

4. Data Analysis and Discussion

4.1 Digital transformation as a staged strategic process

The synthesis indicates that SME transformation is best understood as a progression from foundational adoption to integrated business change. Basic connectivity, secure devices, cloud services, and reliable digital records establish a minimum platform. Process digitisation can then improve invoicing, accounting, inventory, procurement, and customer communication. Integration connects data and workflows across functions. At a more advanced stage, firms redesign value propositions, channels, partnerships, and revenue models. The final competitive effect depends on whether the redesigned model produces value that customers recognise and rivals cannot easily reproduce.

This progression is consistent with the distinction between digitisation, digitalisation, and transformation articulated by Verhoef et al. (2021). It also reflects Vial's (2019) argument that digital technologies can trigger broader organisational changes. The stages should not be interpreted as a rigid maturity ladder: a small firm may create value through a narrow, well-integrated solution without adopting advanced analytics or artificial intelligence. Strategic fit and execution quality matter more than technological sophistication.

Figure 1. A staged pathway from digital adoption to competitive advantage.

Source: Author's conceptual synthesis based on Vial (2019), Verhoef et al. (2021), and OECD (2021a).

4.2 Digital resources and complementary capabilities

Digital resources include hardware, software, connectivity, cloud services, data, platforms, and access to digital markets. These resources can expand what an SME is able to do, but they rarely constitute a lasting advantage in isolation. Bharadwaj (2000) demonstrates the importance of combining IT infrastructure with human resources and IT-enabled intangibles. In practice, an SME may purchase a customer relationship management system, but its value depends on whether employees enter reliable information, managers use the information to make decisions, and customer-facing processes respond to insights.

Leadership capability is a critical complement. Owner-managers often control investment decisions and shape the firm's tolerance for experimentation. Effective digital leadership requires more than enthusiasm for technology: it involves articulating a business problem, selecting a proportionate solution, allocating implementation responsibility, and monitoring outcomes. Workforce capability is equally important. Employees need role-specific digital skills, confidence in new workflows, and an understanding of data quality and security. Without these complements, technology may add administrative burden rather than productivity.

Figure 2 integrates these relationships. Digital resources are converted into value through organisational capabilities and dynamic capabilities. Sensing involves monitoring customers, competitors, regulation, and technology; seizing involves choosing and resourcing a response; reconfiguring involves redesigning processes,

roles, partnerships, and assets. These activities support agility, innovation, and customer experience, which may then contribute to competitive outcomes. The model combines the resource-based and dynamic-capabilities perspectives (Barney, 1991; Teece et al., 1997) with digital-business strategy (Bharadwaj et al., 2013).

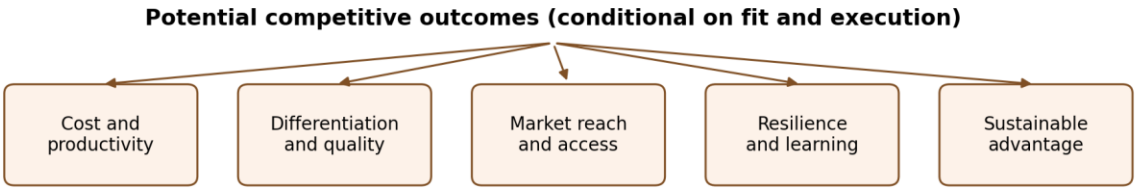

Figure 2. Capability-based explanation of digital transformation.

Source: Author's conceptual synthesis based on Barney (1991), Teece et al. (1997), Bharadwaj (2000), and Bharadwaj et al. (2013).

4.3 Operational efficiency and cost-based advantage

Digital systems can improve efficiency by reducing manual data entry, shortening transaction cycles, improving stock visibility, automating routine tasks, and enabling more accurate coordination. Cloud accounting and digital payment systems may reduce reconciliation effort; inventory tools can help prevent stock-outs and overstocking; workflow applications can make responsibilities and task status more visible. For smaller firms, even incremental improvements can release managerial time for customer service, product development, or supplier relationships.

However, cost reduction should be evaluated as a net outcome. Subscription charges, integration work, staff training, cybersecurity controls, downtime, and vendor switching costs can offset initial savings. A low-cost tool that creates duplicate records or requires repeated manual transfers may increase hidden operating costs. The appropriate assessment compares total cost of ownership with measurable process outcomes such as processing time, error rates, inventory turnover, order fulfilment, and working-capital requirements. Digitalisation creates advantage when process improvements are material, repeatable, and aligned with the firm's operating model.

4.4 Customer value, market access, and differentiation

Digital channels can reduce geographic barriers and allow SMEs to reach customers beyond their immediate locality. E-commerce marketplaces, social media, search tools, digital catalogues, and customer communication platforms can improve discoverability and facilitate direct engagement. Matarazzo et al. (2021b) illustrate how digital tools can support new distribution channels and internationalisation in selected Italian SMEs. Bouwman et al. (2018) also connect social media and big-data use with business-model innovation in European SMEs.

Market access does not automatically produce differentiation. When many firms use the same marketplace or social-media platform, visibility can become expensive and platform rules can shape customer access. Differentiation is more likely when digital channels reinforce a distinctive value proposition: reliable delivery, specialised expertise, customisation, responsive support, traceability, or a trusted community. Customer data can help firms understand preferences and personalise services, but only where data collection is lawful, proportionate, secure, and transparent. A customer-centric digital strategy should therefore balance personalisation with privacy and trust.

4.5 Business-model innovation and new value propositions

Digital transformation can alter the architecture through which a firm creates, delivers, and captures value. Examples include moving from one-time sales to subscriptions, combining physical products with remote support, using digital configuration tools for customised orders, coordinating suppliers through shared platforms, or providing after-sales services through connected channels. Such changes are not simply

technology projects; they require decisions about customer segments, partners, pricing, activities, and revenue logic.

Bouwman et al. (2019) provide evidence that resource allocation to business-model experimentation and stronger strategy implementation practices are associated with better overall performance among the SMEs in their study. This finding reinforces the need for deliberate experimentation. SMEs can reduce risk by testing a new offer with a defined customer group, setting a limited budget, identifying operational dependencies, and specifying success criteria before scaling. The firm should also establish a stopping rule when evidence does not support further investment.

4.6 Innovation, agility, and organisational learning

Digital information can shorten feedback loops. Online reviews, service tickets, transaction records, and website analytics may reveal emerging needs or recurring service failures. When managers review this information regularly and empower employees to act, SMEs can adapt products and processes more quickly. This is an organisational capability, not merely an analytics function. Data that is collected but not interpreted or connected to decisions has little strategic value.

Agility should not be confused with constant change. Excessive experimentation can distract staff and destabilise operations. A disciplined SME distinguishes between reversible experiments and high-risk structural decisions. Small pilots, cross-functional review, and periodic portfolio decisions allow the firm to learn while preserving operational continuity. The dynamic-capabilities framework is useful here because it emphasises the ability to reconfigure resources in response to changing conditions rather than the possession of a fixed set of technologies (Teece et al., 1997).

4.7 Digital transformation barriers and strategic risks

The reviewed evidence identifies interrelated constraints. Financial constraints can prevent investment in infrastructure, integration, and specialist support. Skills constraints may limit adoption and effective use. Weak connectivity or legacy systems can reduce reliability and interoperability. Limited managerial time can delay process redesign. Cybersecurity incidents, data loss, fraud, privacy violations, and vendor lock-in can undermine trust and continuity. OECD (2021a) identifies these barriers as persistent features of SME digitalisation, while Kergroach (2021) highlights the tendency for adoption gaps to widen as technologies become more sophisticated.

These barriers interact. A firm that lacks internal IT expertise may depend heavily on a vendor, increasing lock-in and limiting its ability to evaluate security claims. A firm that adopts multiple applications without data governance may create fragmented records and inconsistent customer information. A firm that moves sales online without strengthening fulfilment may damage its reputation through late deliveries. Therefore, risk management should be embedded in transformation planning rather than treated as a final compliance check.

4.8 Comparative synthesis of the evidence

Table 1 compares the major perspectives and their contributions. The comparison shows that no single theoretical lens is sufficient. The resource-based view explains why complementary resources matter; dynamic capabilities explain adaptation; digital-business strategy explains the fusion of technology and business choices; and SME-focused studies illustrate the role of business-model experimentation. Institutional reports add the enabling and constraining environment.

Table 1: compares the major perspectives and their contributions

Source / perspective	Main contribution	Limitation or boundary	Implication for SMEs
Barney (1991), resource-based view	Explains advantage through valuable, rare and difficult-to-imitate resources	General theory; does not specify digital implementation steps	Build firm-specific data, routines, expertise and relationships around technology
Teece et al. (1997),	Explains sensing, seizing	Abstract framework;	Create routines for

dynamic capabilities	and reconfiguring in changing environments	operationalisation can be difficult	scanning, experimentation and process renewal
Bharadwaj (2000), IT capability	Links IT infrastructure, human IT resources and intangibles with performance	Not SME-specific; context and period differ	Invest in skills and IT-enabled routines, not infrastructure alone
Bharadwaj et al. (2013), digital business strategy	Treats digital strategy as integrated with business strategy	Conceptual editorial perspective rather than SME field test	Connect technology choices to market positioning and value creation
Bouwman et al. (2018, 2019), SME studies	Links digitalisation, business-model innovation and implementation practices with performance	European samples; firms actively using digital tools	Fund experimentation and implementation, then evaluate outcomes
Matarazzo et al. (2021), SME cases	Shows pathways to new channels and internationalisation	Three cases; limited generalisability	Use digital channels to reinforce a clear value proposition
OECD (2021a, 2021b, 2024), institutional evidence	Documents skills, finance, infrastructure, security and digital-gap challenges	Aggregated and country-dependent evidence	Tailor support to firm size, sector, readiness and risk

4.9 Integrated analytical framework

The synthesis suggests a conditional relationship rather than a simple direct effect. Digital transformation contributes to competitive advantage when digital resources are aligned with strategic priorities and combined with leadership, workforce skills, process redesign, data governance, and external partnerships. These capabilities enable operational efficiency, differentiation, market reach, innovation, and resilience. The strength of the relationship is moderated by firm size, sector, market turbulence, infrastructure, access to finance, regulatory conditions, and the firm's starting level of digital maturity.

The framework also highlights feedback. Competitive outcomes can generate additional resources and learning, allowing the SME to invest in further transformation. Conversely, poor implementation can consume scarce capital, reduce trust, and weaken the firm's ability to respond. This reinforces the need for staged investment and measurement.

4.10 Implementation roadmap for SMEs

A practical transformation programme should begin with a diagnosis of business priorities rather than a catalogue of available technologies. Managers should identify customer pain points, costly or error-prone processes, data gaps, and supply-chain dependencies. The next step is to prioritise a small number of use cases according to expected value, feasibility, risk, and staff readiness. Pilot projects should have clear owners, baseline measures, defined budgets, and review dates. Successful pilots can then be integrated into workflows and scaled, while unsuccessful experiments should generate learning without becoming permanent costs.

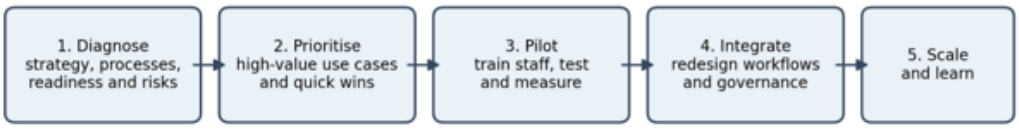

Figure 3. A resource-conscious digital transformation roadmap.

Source: Author's synthesis of the implementation and capability themes in OECD (2021a), Kergroach (2021), and Bouwman et al. (2019).

4.11 Performance measurement

A balanced measurement system should connect digital activity to business outcomes. Adoption measures, such as the number of digital tools or staff trained, are useful implementation indicators but do not establish competitive advantage. Process measures may include order cycle time, error rates, inventory accuracy, customer response time, and cost per transaction. Market measures may include repeat purchase, customer retention, conversion, geographic reach, and complaint resolution. Strategic measures may include the speed of new-product development, revenue from new channels, supplier integration, and the ability to maintain service during disruption.

Measures should be selected before implementation and reviewed against a baseline. Where feasible, managers should compare performance across periods or between pilot and non-pilot processes while accounting for seasonal and market changes. Financial indicators should be interpreted alongside non-financial outcomes because digital transformation may initially require investment before benefits emerge. A narrow focus on short-term return can lead firms to abandon capability-building projects whose value develops over time.

5. Conclusion

This paper examined how small and medium enterprises can achieve competitive advantage through digital transformation. The review indicates that digital technologies create opportunities to improve processes, access customers, use information, coordinate supply chains, and experiment with business models. However, the presence of technology is not equivalent to strategic transformation. Competitive value emerges when technologies are aligned with business priorities and embedded in organisational capabilities that competitors cannot easily reproduce.The paper's central contribution is an integrated capability-based framework. Digital resources provide the technical foundation; leadership, skills, and process ownership enable effective use; dynamic capabilities support sensing, seizing, and reconfiguring; and value-creation mechanisms translate these activities into efficiency, differentiation, market reach, innovation, and resilience. The framework also recognises that outcomes are moderated by finance, infrastructure, sectoral conditions, regulation, and security risks.For SME managers, the practical implication is to begin with business problems and customer needs, not technology trends. Firms should assess readiness, prioritise a small number of high-value use cases, pilot solutions, train employees, strengthen data and cybersecurity governance, and scale only when evidence supports expansion. Digital transformation should be measured through operational, customer, financial, and strategic indicators. Managers should also avoid excessive dependence on a single platform or vendor and should preserve the ability to access, protect, and use their own business data.For policymakers and support institutions, the findings point to the importance of affordable infrastructure, practical training, trusted advisory services, accessible finance, cybersecurity assistance, and interoperable digital public services. Support programmes should recognise the diversity of SMEs rather than assume that all firms require the same technology or level of sophistication.

The study is limited by its selective secondary-source design and the heterogeneity of the evidence reviewed. It does not test causal relationships or estimate the average effect of digital transformation on SME performance. Future research should test the proposed framework using longitudinal and multi-sector samples, compare micro, small, and medium enterprises, and examine how leadership, skills, agility, and cybersecurity shape outcomes. Research in emerging economies, including India, would be particularly valuable because infrastructure, informality, financing conditions, and public digital platforms may influence the transformation pathway. Overall, sustainable competitive advantage is most likely when SMEs treat digital transformation as a continuing capability-building process that connects technology with customer value, organisational learning, and strategic renewal.
